CARBON MONITORING

NATIONAL OCEANIC AND ATMOSPHERIC ADMINISTRATION • UNITED STATES DEPARTMENT OF COMMERCE

Continuing the legacy of Dr. Charles D. Keeling in monitoring carbon dioxide, NOAA's Office of Oceanic and Atmospheric Research (OAR) has a long history in monitoring greenhouse gases. OAR strives to record accurate measurements of greenhouse gases to improve our understanding of the global carbon cycle and how greenhouse gases affect global and regional climate and the world's oceans.

1957 The U.S. Weather Bureau provides funding to Charles D. Keeling to begin monitoring carbon dioxide (CO_2) at the South Pole and Mauna Loa Observatory (MLO), Hawaii, as part of the International Geophysical Year. The record continues today under auspices of both NOAA and Scripps Institution of Oceanography.

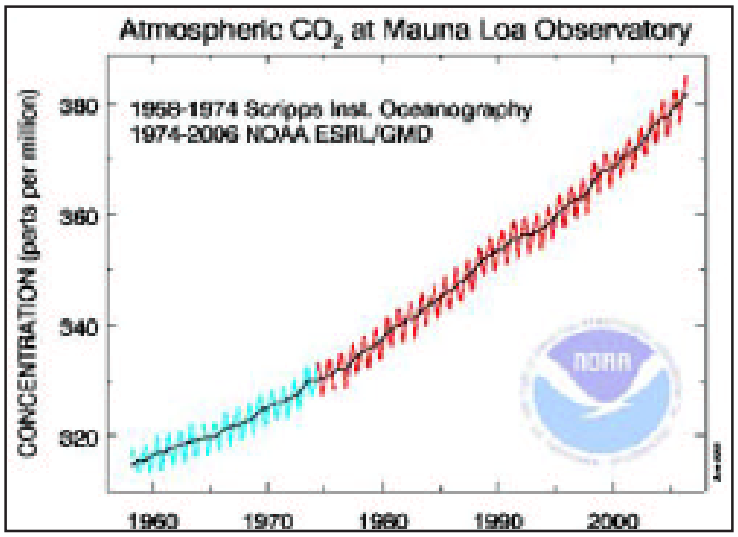
1958 Keeling starts the first direct continuous atmospheric measurements at NOAA's station near the summit of Mauna Loa. The MLO eventually becomes part of what is now NOAA's Earth System Research Laboratory. MLO is one of NOAA's five baseline observatories and, with more than 60 national and international partners collecting weekly flask samples around the globe, is taking the pulse of the atmosphere. The MLO and South Pole data sets are the first to show the rate at which carbon dioxide levels in the atmosphere are rising.

1968 Atmospheric measurements begin in 1968 at Niwot Ridge, Colo., and NOAA has monitored CO_2 worldwide since the early 1970s.

1970 NOAA is formed.

1989 The Climate and Global Change Program (C&GCP) office is established to conduct research on global climate change phenomena and reports directly to the NOAA administrator.

1990 The Climate Monitoring and Diagnostics Laboratory is formed from parts of NOAA's Air Resources Laboratory (ARL). In 1990, C&GCP becomes the Office of Global Programs (OGP) under OAR. Its primary mission is to provide scientific research on climate variability, predictions, and assessments, and to better understand the global climate system. A modeling investigation by NOAA's Geophysical Fluid Dynamics Laboratory demonstrates a linkage between chemical depletion of ozone and the physical greenhouse warming effect.



Referred to as the Keeling Curve, this graph shows the monthly mean atmospheric carbon dioxide at Mauna Loa Observatory, Hawaii.

1992 Light aircraft carrying automated flask sampling packages developed by NOAA's Earth System Research Laboratory begin sampling the profiles of carbon cycle gases, providing much needed regular measurements of the vertical profile of such gases over continental areas. NOAA monitors atmospheric greenhouse gas concentrations to document rates of increase and to estimate the magnitude of sources and sinks from atmospheric concentration patterns. This information will be important in defining policies addressing the human contribution to the greenhouse effect and climate change.

1992 First tall tower measurements of carbon cycle gas gradients starts near Grifton, N.C.

1995-2003 NOAA's Earth System Research Laboratory (ESRL) develops and maintains the world standard references for CO_2 (1995), CO (1999), CH_4 (2003), and N_2O (2003).

1999 Interactive Data Visualization allows easy Web access to data and providing up-to-date plots of greenhouse gas data from NOAA's global carbon network of more than 60 sites.

2000 NOAA begins participating in the North American Carbon Program.

(continued from previous page)

2005 The Climate Monitoring and Diagnostics Laboratory is merged with the radiation branch of Air Resources Laboratory to form the Global Monitoring Division of the Earth System Research Laboratory.

2005 The NOAA Annual Greenhouse Gas Index is introduced, designed to enhance the connection between scientists and society by providing a normalized standard that can be easily understood and followed.

2007 Carbon Tracker is launched, providing distributions of carbon dioxide, weather, carbon fluxes, and their uncertainties over space and time. .
